overview

TECHNISCHE
UNIVERSITÄT
DARMSTADT

- multimodal communication in the target domain
- cohesion and coherence in multimodal documents
- analysis scheme
- conclusions / outlook

„[...] every linguistic act, spoken or written, takes place over more than one 'mode' or channel of communication“

„The study of 'monomodal' texts traditional in linguistics and other text-based investigations is thus revealed as an abstraction whose validity is questionable.“

(Bateman et al. 2002)

multimodal communication in the target domain

- target domain: data processing in construction, a subdomain of mechanical engineering
- self-characterisation: „the drawing is the language of the engineer“ (Reiner Anderl)
- semiotic resources:
 - natural language
 - visual representations such as pictures, schematic figures, sketches etc.
 - symbolic representations: formulae, diagrams, numerical data etc.
 - intermediary forms: tables, representations of data structures
 - virtual models such as CAD (Computer Aided Design) models

multimodal communication in the target domain

3 Rapid Prototyping Techniques

Most commercially available rapid prototyping machines use one of six techniques. At present, each technique essentially limit the capabilities of rapid prototyping machines, so that each only covers certain materials or the T.S.

3.1 Stereolithography

Patented in 1981, stereolithography created the rapid prototyping revolution. The technique builds three-dimensional models from liquid photopolymer resins that solidify when exposed to ultraviolet light. As shown in the figure below, the model's build-up is completed in several parallel layers. The surface is a mix of liquid epoxy or acrylic resin. A low-power highly focused UV laser traces out the first layer, solidifying the model's cross section while leaving excess resin liquid.

Figure 1 Schematic diagram of stereolithography.¹⁷

Next, an elevator systematically lowers the platform into the liquid polymer. A receptor on top of the solidified figure with liquid, and the laser moved laterally along the flat. This process is repeated until the prototype is complete. Afterwards, the solid part is removed (often the not used) of excess liquid. Supports are broken off and the model is then placed in an ultrasonic bath for complete curing.

html-page: teaching materials

Using this principle and a surface, rather than liquid, the process is used to create solid models. The process is called Selective Laser Sintering (SLS). The process is similar to stereolithography, but instead of a liquid resin, a powder is used. The powder is a mix of plastic and metal particles. A laser beam is used to sinter the powder, creating a solid layer. The process is repeated until the prototype is complete. Afterwards, the solid part is removed (often the not used) of excess powder. Supports are broken off and the model is then placed in an ultrasonic bath for complete curing.

motivation

TECHNISCHE
UNIVERSITÄT
DARMSTADT

- how does the target discipline construe meaning multimodally?
- how is domain knowledge construed in different semiotic resources?
- how is multimodal semiosis instantiated in different types of documents in the target domain?

Technische Universität Darmstadt • Institut für Sprach- und Literaturwissenschaft

12

question: intersemiosis

TECHNISCHE
UNIVERSITÄT
DARMSTADT

- how do multiple modalities interact in multisemiosis?
- how is coherence achieved?

focus on intersemiosis:

- do they jointly contribute to the coherence of a multimodal document?
- **how** do they jointly contribute to the coherence of a multimodal document?

detour: some features of coherent (multimodal) text

TECHNISCHE
UNIVERSITÄT
DARMSTADT

- linearity
- rhetorical structure
- logical continuity
- multidimensional relations between sense units within semiotic resources
- surface cohesive devices
(recurrence / repetition; substitution; ellipsis ...)
- interactivity

detour: coherence in multimodal documents

TECHNISCHE
UNIVERSITÄT
DARMSTADT

- extension of the notions of coherence and cohesion to multimodal communication artefacts
- how do the concepts transfer?
- what are the necessary extensions / constraints?

methodological issue

TECHNISCHE
UNIVERSITÄT
DARMSTADT

- the lack of a rich and well established descriptive inventory – such as that available for natural language – for the description of other modalities
- models for the interaction between different modalities in multimodal documents
- the lack of well-organised data resources for the computer-aided study of multimodal documents

additional issues

TECHNISCHE
UNIVERSITÄT
DARMSTADT

- resources for the study of multisemiosis
 - established methodology
 - multimodal corpora
 - tools for annotation
 - annotation standards
 - query

research context

TECHNISCHE
UNIVERSITÄT

ellipsis in text

As shown in the figure below, a [feeder/collector](#) mechanism advances the sheet over the build [platform](#), where a base has been constructed from paper and double-sided foam tape. Next, a [heated roller](#) applies pressure to bond the paper to the base.

A focused [laser](#) cuts the outline of the first layer into the paper and then cross-hatches the excess area (the negative space in the prototype). Cross-hatching breaks up the extra material, making it easier to remove during post-processing. During the build, the excess material provides excellent support for overhangs and thin-walled sections. After the first layer is cut, the platform lowers out of the way and fresh material is advanced.

inter-modal cohesion: conjunction in text and figure

TECHNISCHE
UNIVERSITÄT
DARMSTADT

[...] solid ground curing (SGC) is somewhat similar to stereolithography (SLA) in that both use ultraviolet light to selectively harden photosensitive polymers. Unlike SLA, SGC cures an entire layer at a time. Figure 5 depicts solid ground curing, which is also known as the solider process. **First**, photosensitive resin is sprayed on the build platform. **Next**, the machine develops a photomask (like a stencil) of the layer to be built. This photomask is printed on a glass plate above the build platform using an electrostatic process similar to that found in photocopiers. The mask is **then** exposed to UV light, which only passes through the transparent portions of the mask to selectively harden the shape of the current layer.

teaching materials / teacher to student:

[ctd. from annotation slide] As shown in the figure below, a feeder/collector mechanism advances the sheet over the build platform, where a base has been constructed from paper and doubles-sided foam tape.

Next, a heated roller applies pressure to bond the paper to the base.

A focused laser cuts the outline of the first layer into the paper and then cross-hatches the excess area (the negative space in the prototype).

Cross-hatching breaks up the extra material, making it easier to remove during post-processing.

During the build, the excess material provides excellent support for overhangs and thin-walled sections.

After the first layer is cut, the platform lowers out of the way and fresh material is advanced.

The platform rises to slightly below the previous height, the roller bonds the second layer to the first, and the laser cuts the second layer.

Scoping:
